ABSTRACT

The purpose of this study is to know the concentration of boron and irradiation times which optimizes the treatment of breast cancer using the BNCT method. This research was conducted by using MCNPX simulation which outputs are flux neutron, neutron scattering dose and gamma dose. The neutron source used is the BSA D-D Neutron generator model. The independent variable of this research is the boron concentration injected into the cancer. The dependent variable is the total dose rate and irradiation time which determines the effectiveness of BNCT therapy. The controlled variables are the output of the neutron flux, dose and gamma neutron scattering dose. The results showed that in the range of 70-150 $\mu\text{g/g}$, the dose rate received by cancer increases with increasing the concentration of boron-10. If the dose rate is increased, the irradiation time interval will be faster. The Boron dose of 70 $\mu\text{g/g}$ and the dose rate of irradiation 0.00293603 Gy/sec needs an irradiation time of 409.43 minutes; the boron dose of 90 $\mu\text{g/g}$ and the dose rate of irradiation 0.00241049 Gy/sec needs an irradiation time of 345.71 minutes; the boron dose of 110 $\mu\text{g/g}$ and the dose rate of irradiation 0.00271236 Gy/sec needs an irradiation time of 307.24 minutes; the boron dose of 130 $\mu\text{g/g}$ and the dose rate of irradiation 0.00303389 Gy/sec needs an irradiation time of 274.67 minutes; and the boron dose 150 $\mu\text{g/g}$ and the dose rate of irradiation 0.00334565 Gy/sec needs an irradiation time of 249.08 minutes. The Optimum concentration of boron is 150 $\mu\text{g/g}$ with irradiation time of 249.08 minutes.

1. INTRODUCTION

Cancer is the uncontrolled proliferation of cells or tissues. As mention by the Indonesian Health Ministry (2013), cancer is the 2nd leading cause of death (13% from all 22% death) caused by non infected diseases in the world [Oemita et al, 2011]. Details of cancer caused death in Indonesia is 103,100 males and 92,200 females [WHO, 2014]. Frequent cancer cases that occur in males include lung cancer, prostate cancer and cholesterol cancer that translates to approximately 21.8% of all cancer cases, while in females, breast cancer equates to approximately 21.4% from all cancer cases.

BNCT is a new radiotherapy method that is being developed after many cancer therapies have displayed negative side effects towards patients. These methods include radiotherapy, surgery, chemotherapy and/or the combination of the three. Among the three methods as mentioned, BNCT is one radiotherapy method that has the potential to be developed.

Another important thing beside neutron sources and boron carrier for BNCT is setting the radiation dose received by the body, and so considering the quality of neutron radiation which is used for treatment [Huang, 2009]. These dosing devices must ensure the safety and optimal treatment. Safety means that the side effects of the treatment are limited to as little as possible. Optimal means the organ

* E-mail: sardjono.batan@gmail.com

affected by cancer receives as much treatment dose as possible and has an irradiation time that is as short as possible.

Research of BNCT has been done by Dian Noviati (2013) for breast cancer therapy. This research compares irradiation time in breast cancer with a boron concentration range of 20-70 $\mu\text{g/g}$ using MCNP5. The results show that for BNCT the minimum irradiation time occurs when the boron concentration is 70 $\mu\text{g/g}$ [Noviati, 2013]. Therefore, research about the dose received for breast cancer needs to be done so that safety and the optimum dose for BNCT treatment can be achieved.

2. MATERIALS AND METHODS

Design of the BSA and breast cancer were done using MCNPX. Dose distribution and irradiation time has been performed and calculated for each variation of boron concentration, i.e. 70 $\mu\text{g/g}$, 90 $\mu\text{g/g}$, 110 $\mu\text{g/g}$, 130 $\mu\text{g/g}$, and 150 $\mu\text{g/g}$. The neutron energy used are epithermal neutrons with a flux of $8.05 \times 10^8 \text{ neutron/cm}^2 \text{ s}$ [Gulo, 2012].

The cancer cells were made as a sphere with a diameter of 3 cm, while the skin is a semi-circular shape with a thickness of 0.25 cm, ribs are tubes with diameters of 1.5 cm and 15 cm in length, and the geometry of the breast is a half circle with a diameter of 14 cm. In modeling, the cancer cells are considered to be situated in the middle of the breast. Cancer cell density is assumed to be 10% greater than the density of the normal breast tissue so that the density-value is 1.12 g/cm^3 .

This research was conducted in several steps. The first step was to prepare the data and study library material. Second, to create the geometry of the cancer and healthy tissue that is placed in front of the BSA, then calculate the fraction of atoms to be used in data cards in MCNPX variation in the dose range of 70-150 mg/g . This is followed by running the program on each of the boron concentrations. The output of MCNPX will be analyzed to calculate the radiation dose and the time required for irradiation.

3. RESULTS AND DISCUSSION

Epithermal neutron flux is used in BNCT therapy so that the neutron is moderated when it passes through the body into thermal neutrons so that the energy received by the cancer under the surface is low, which reduces the dose received by the skin. Figure 2 (a and b) shows a side view of the NG BSA design and breast tissue. Every human being has varying characteristics and different breast sizes but the simulated breast size is based on the average breast size.

Fig 2. Neutron flux due to the depth in tissue

Based on Figure 2, it is known that the epithermal neutron flux has a greater value than the thermal neutron flux, while the value of thermal neutron flux is below the epithermal

neutrons and gradually declines faster until it approaches 0.00. Epithermal neutron flux increased with the depth of tissue, before declining. This happens because of the decreased energy of epithermal neutron (moderated) into thermal neutrons that interact with components of the tissue. The flux values obtained by the tissue will also affect the value of the total absorbed dose received by the tissues of the body.

Thermal and epithermal neutron flux at different tissue depths were obtained after concentrations of 10B were varied in the cancer. The fourth dose also has each weight factor. Differences in factors are influenced by the sensitivity of the target tissue and Linear Energy Transfer (LET) of each dose. The weighting factors affect the value of the absorbed dose received by the tissues of the body. Table 1 shows the distribution of the dose rate in cancer tissues with various concentrations of boron.

Table 1. Dose rate in cancer cell

Konsentrasi boron ($\mu\text{g/g}$)	Laju dosis (Gy/detik)				
	$\dot{D}_b$	$\dot{D}_p$	$\dot{D}_n$	$\dot{D}_g$	$\dot{D}_{\text{total}}$
70	3,21587E-04	8,94055E-05	3,47427E-04	4,03500E-04	2,93603E-03
90	4,42655E-04	8,94055E-05	1,82668E-05	4,05389E-04	2,41049E-03
110	5,23854E-04	8,65683E-05	1,78660E-05	4,08407E-04	2,71236E-03
130	6,10203E-04	8,53242E-05	1,75890E-05	4,06384E-04	3,03389E-03
150	6,93031E-04	8,39852E-05	1,73210E-05	4,08210E-04	3,34565E-03

Total dose rate at the cancerous tissue tends to increase for each increased boron concentration. This happens because healthy tissue only receives 0.3% of the boron the cancerous tissue receives. This value is obtained from the infusion method i.e. with a ratio of 10: 1. Cancer received high doses, as high as the boron concentration that was injected into the body. This will speed up the healing process.

Table 2 shows the irradiation time required for each of the different boron concentrations in cancer tissue.

Table 2. Irradiation time due to boron concentration.

Konsentrasi boron ($\mu\text{g/g}$)	Waktu radiasi (detik)	Waktu radiasi (Menit)
70	24565,80	409,43
90	20742,64	345,71
110	18434,17	307,24
130	16480,47	274,67
150	14944,79	249,08

In Table 2, the boron concentration of 70 $\mu\text{g/g}$ required an irradiation time of 409.43 minutes while the highest concentration of 150 $\mu\text{g/g}$ needed a faster time of 249.0824 minutes. Fast irradiation time is reached when the boron concentration is high, so that the dose rate in the cancer cell is high. This is because the high boron concentration can increase the probability of interaction between neutron and boron, thus affecting the production of the alpha particle which is used to kill the cancer.

Skin is one of the body tissues that will experience acute effects when exposed to radiation. The acute effects of this will occur after irradiation is done. Effects will arise normally in the form of erythema, moist desquamation and ulceration (pus). Erythema occurs when the skin receives a dose larger than 6 Gy while moist desquamation and ulceration occurs after receiving a dose of 20-25 Gy. Therefore, the number of doses in the skin must be taken into consideration in the implementation of BNCT treatment so that the skin receives a dose of less than 6 Gy to avoid the effects of erythema (Novianti, 2013). Table 19 shows the results of the dose absorbed by each organ according to the result of calculations.

Table 3. Type Dose absorbed y each organs.

Konsentrasi boron ($\mu\text{g/g}$)	Dosis Serap (Gy)			
	Kulit	Kanker	Payudara	Rusuk
70	2,9	50	5,2	2,7
90	2,4	50	4,4	2,3
110	2,1	50	3,8	1,9
130	1,9	50	3,5	1,8
150	1,8	50	3,1	1,7

The table shows that the dose received by skin is less than 6 Gy when using a boron concentration of 150 $\mu\text{g/g}$. The absorbed dose in the skin declines steadily with increasing concentrations of boron. The dose absorbed by other organs is reduced when granting enlarged concentrations as well, which is expected and

is below the safe limit for each organ. In this study, the dose received by the skin, breast healthy tissue and ribs is at a concentration of 150 ug/g, which is 1.8 Gy, 3.1 Gy and 1.7 Gy, respectively. This shows that there are no side effects in the skin because the dose is within the safe level, ie below 2 Gy, since epilation and dry desquamation occurs in the range of 3-12 Gy.

4. CONCLUSION AND REMARKS

It can be concluded that the higher the concentration of boron in breast cancer therapy using BSA NG results in a lower irradiation time when the dose is within 70-150 mg/g. The optimal dose of boron based on the results of the research is at a concentration of 150 ug / g. The time required for the irradiation of breast cancer increases rapidly at concentrations greater than 150 ug/g, with an irradiation time of 249.08 minutes or 4 hours 15 seconds.
